

Enable SSL/VPN for your user (snippet)

Before an invited user can download and install their SSL VPN, the account administrator must add the following permissions to their account:

- Write SSL VPN Devices and Users
- Read SSL VPN Devices and Users
- Read Virtual Data Centers

Additionally, the account administrator must enable the account to access the SSL VPN client:

1. In the Armor Management Portal (AMP), in the left-side navigation, click **Infrastructure**.
2. Click **SSL VPN**.
3. Click **Members**.
4. In the top bar, select the data center that corresponds to your virtual machine.
 - If you have virtual machines in multiple data centers, then you must configure the user for each data center. (Also, you must download the client for every data center you use.)
5. Under **Active Members**, type and select the desired username.
 - The user can now access to AMP to download their SSL VPN client.
